## Counterparty Casino: The need to address a systemic risk

By Jon Gregory

# The Role of a CVA Group

# History of Counterparty Risk and CVA

## CCR / CVA Timeline

In a few short years we have seen a paradigm shift in CCR with the transition from Passive to Active management of CVA that requires ever more accurate and more frequent CVA calculations – daily, intra-daily, and real-time

Source: Algorithmics

# Why a CVA Group?

- Requirements to mark-to-market CVA in all derivatives positions
- This creates two obvious key problems
  - How to allocate the CVA across businesses / trading desks
  - How to avoid the volatility of all the CVA due to market movements (specifically credit spreads and volatility)
- Creates the need for an institution to have a specialised group to tackle this across all businesses
  - Cross asset focus
  - Mostly trading (not risk management) driven

# CVA

# CVA (Credit Value Adjustment)

- CVA is the price of counterparty risk (expected loss) and is a cost

$$\text{Risky Derivative} = \text{Derivative} - \text{CVA}$$

- Crucial to be able to separate valuation of derivatives and their CVA (below formula assumes no wrong way risk)

$$CVA(t) = (1 - \delta_C) \int_t^T EE(u) dPD_C(u)$$

Percentage  
recovery value

Expected exposure  
including discounting (how  
much we expect to lose)

Default probability  
(how likely is counterparty  
to default at this time)

# CVA (Credit Value Adjustment)

- CVA is the price of counterparty risk (expected loss) and is a cost

$$\text{Risky Derivative} = \text{Derivative} - \text{CVA}$$

- Crucial to be able to separate valuation of derivatives and their CVA (below formula assumes no wrong way risk)

$$CVA(t) = (1 - \delta_C) \int_t^T EE(u) dPD_C(u)$$

Percentage  
recovery value

Expected exposure  
including discounting (how  
much we expect to lose)

Default probability  
(how likely is counterparty  
to default at this time)

# But CVA is Very Complex

- CVA represents an option on an underlying derivative
  - CVA calculation always harder than pricing the derivative itself
- Need the default probability (and recovery rate) of the counterparty
  - Often market implied probabilities are not known (no CDS market)
- Derivatives are subject to netting agreements
  - Need to price all other trades with this counterparty as well as trade in question
  - All correlations (same asset class, cross-asset class must be known)
- Wrong way risk
  - Linkage between default probability and exposure at default
- Collateral agreements, break clauses etc

# CVA Trading is a Challenge

- Management of a cross asset credit contingent book
- Trade on only one side of the market
- Should give credit for all risk mitigants (netting, collateral, break clauses)
- Hedging CVA is challenging and often simply not possible

# Trading Book CVA?

- CVA is a market price *by association* to the underlying OTC derivative
  - Consistent with derivatives valuation
  - But trading function for CVA is very difficult to run
  - Hedging is extremely difficult or impossible
- Derivatives are essentially exotic loans and so *by association* some CVA could be treated outside the trading book
  - Consistent with loan book management
  - Pricing / provisioning / regulation is easier
  - Little or no hedging required
- Insisting on the market approach may just lead to worse problems

# Active Management of CVA?

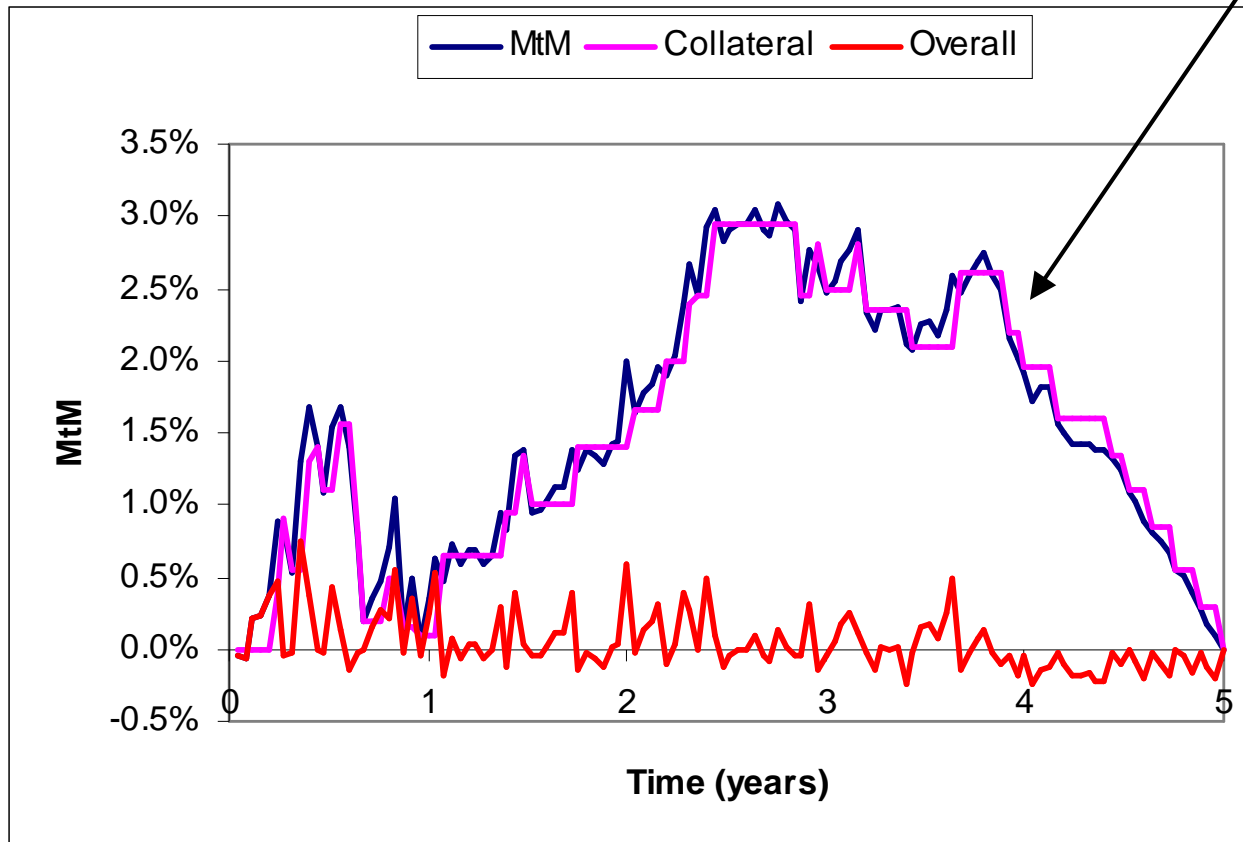

*“... given the relative illiquidity of sovereign CDS markets a sharp increase in demand from active investors can bid up the cost of sovereign CDS protection. CVA desks have come to account for a large proportion of trading in the sovereign CDS market and so their hedging activity has reportedly been a factor pushing prices away from levels solely reflecting the underlying probability of sovereign default.”*

## **Bank of England Q2**

# The Growing Use of DVA

# CVA for CSA Counterparties

10-day remargin period assumed

# Collateralised CVA Example

<b>Assumption</b>	<b>CVA (bps)</b>
10-day remargin period	0.51
+ Minimum transfer amount of 0.5%	0.69
+ Threshold of 1.0%	1.57
No collateral	2.79

# Unilateral CVA in the Old Days

	Credit Rating	Credit spread (bps)
<b>Bank</b>	Aa1/AA+	10-15
<b>Corporate</b>	A3/A-	200-300

- Bank has no default risk
  - Bank charges corporate unilateral CVA
  - If corporate asks for banks default probability to be taken into account, they get laughed at
- No CVA charges in interbank market (collateralised, banks won't default)
- When bank credit quality deteriorates, market becomes gridlocked

# Pricing Bilateral Counterparty Risk

- Bilateral CVA considers also an institutions own default (this formula assumes independent of defaults)

$$BCVA(t) = (1 - \delta_C) \int_t^T \underbrace{EE(u)}_{\text{Expected exposure}} \underbrace{[1 - PD_I(u)]}_{\text{Probability we haven't yet defaulted}} \underbrace{dPD_C(u)}_{\text{Probability counterparty defaults}} \quad \text{CVA}$$

$$-(1 - \delta_I) \int_t^T \underbrace{NEE(u)}_{\text{Negative expected exposure}} \underbrace{[1 - PD_C(u)]}_{\text{Probability counterparty hasn't yet defaulted}} \underbrace{dPD_I(u)}_{\text{Probability we default}} \quad \text{DVA}$$

Own percentage recovery value

# How to Realise DVA

- Go bankrupt
  - Usually not a popular choice
- Unwinds or novations
  - An institution may realise a DVA gain if a trade is unwound in the future (e.g. banks unwinding transactions with monolines)
- Hedging
  - DVA much harder to hedge than CVA - cannot sell CDS protection on yourself!
  - Buy back your own debt (not really a dynamic hedge) – do you have the cash?
  - Sell CDS on another counterparty (who is highly correlated with you) – give wrong-way risk to buyer of protection – careful who you choose (Lehman)
- Funding arguments
  - Double counting of DVA and funding

# Regulatory Aspects

# Regulatory Reaction to the Credit Crisis

- BCBS Committee (Dec 2009)
  - .... where current treatment did not adequately capitalise for risks during the crisis ☺
- Key problems identified
  - Capitalisation of CVA volatility (2/3 of counterparty risk related losses during crisis?)
  - Initial margining (capital to give incentive for adequate initial margin through cycle)
  - Central counterparties not utilised
  - Close-out periods
  - Interconnection of financial institutions
  - Lack of back-testing and stress testing
  - Wrong-way risk

# The Problems With CVA VAR

- Recent changes
  - Remove the multiplier of 5 (scaling from 10 days to 1 year) ☺
- Only single name hedges (CDS, CCDS) given capital relief
  - Now seemingly will give some relief for index hedges
  - But how? And will this not be encourage procyclicality?
- Methodology
  - Intended to capture in a simple way the credit spread risk within CVA
  - Actually, it is not the optimal way to do this and can lead to non economic results (Rebonato et al.)
- Motivation
  - OTC derivatives are relatively precisely valued, their VAR is much harder to quantify
  - CVA itself is hard to quantify so CVA VAR is surely a major challenge?

# Central Counterparties

# CCPs
